electronic calculators. Using the polynomial approximations and a suitable calculator, it is possible to duplicate existing reference source tabular values directly, obviating the need for interpolation or further reference to the tables per se. The accuracy of the calculated values can be within 0.5% of the tabular values. The polynomial coefficients are given in the International System of Units (SI). Methods are presented to calculate the temperature corresponding to a given property value. Extrapolation features of the polynomials are discussed.

ABSTRACT

Based on a least-squares polynomial approximation, a procedure is introduced for calculating existing tabular values of thermodynamic and transport properties for common gases. The specific heat at constant pressure is given for 238 gases, the thermal conductivity for 55 gases, the dynamic viscosity for 58 gases, and the second and third virial coefficients for 14 gases. At sufficiently low pressures, ideal gas behavior prevails and temperature may be used as the single independent variable. The algorithm for nested multiplication is presented, optimized for hand-held or desktop electronic calculators. Using the polynomial approximations and a suitable calculator, it is possible to duplicate existing reference source tabular values directly, obviating the need for interpolation or further reference to the tables per se. The accuracy of the calculated values can be within 0.5% of the tabular values. The polynomial coefficients are given in the International System of Units (SI). Methods are presented to calculate the temperature corresponding to a given property value. Extrapolation features of the polynomials are discussed.

I. INTRODUCTION

Many important thermodynamic and transport properties of gaseous elements and compounds can be expressed purely and accurately as functions of temperature. The perfect gas behavior of simple compressible substances is a well documented example¹⁻³. Data tables for such single-variable functions may be approximated with curve-fitting techniques reducing the tabular information to polynomial or exponential forms. Given these equations and a handheld or desktop electronic calculator, a user may retrieve the tabular information accurately and conveniently without interpolation or further reference to the original data sources. The objective of this work is to provide sufficiently simple polynomial fits which together with a modern electronic calculator present the most convenient method of handling the calculation of thermodynamic properties accurately. In all but the most detailed numerical work, the information presented here should prove to be advantageous over present tabular, graphical, or other methods. This report significantly expands the scope of our earlier work⁴ by including basic properties of a large number of elements and compounds.

The gas properties for which polynomial equations are presented comprise the specific heat at constant pressure [$C_p(T)$] for 238 gases in Appendix A, the thermal conductivity [$k(T)$] for 55 gases in Appendix B, the dynamic viscosity [$\mu(T)$] for 58 gases in Appendix C, and the second and third virial coefficients for 14 gases in Appendix D. The accuracy of reproduction of source data is within 0.5%. The correlating equations are presented in the International System of Units (SI). To further enhance the usefulness of this work, methods are given to reverse the dependent and independent variables (i.e., to calculate the temperature corresponding to a given property

value); these methods consist of either polynomials for the inverse calculation as given in the Appendixes or the iterative procedures discussed in Section 5.

In any effort such as this, consideration must be given to the range of validity of the polynomial fit in addition to its accuracy. Section 2 addresses these important topics. The possibility and limitation of extrapolation is discussed in Section 4. Also, the technique of nested multiplication is discussed in Section 3; this technique is a "natural" for the majority of electronic calculators presently available and provides for the convenient use of the information presented herein.

It should be noted that for a perfect or ideal gas (with variable heat capacities) having C_p in polynomial form is particularly useful. This is because the polynomials may be integrated easily, without risking any decrease in the accuracy of the results. The well known relations for a perfect or ideal gas are summarized below and Ref. 5 expands on the technique for generating the gas tables.

$$C_v = C_p - R \quad [\text{specific heat at constant volume}]$$

$$\gamma = C_p / (C_p - R) \quad [\text{ratio of heat capacities}]$$

$$h = \int C_p dT \quad [\text{enthalphy}]$$

$$u = h - RT \quad [\text{internal energy}]$$

$$\phi = \int C_p \frac{dT}{T} \quad [\text{entropy function}]$$

While the simplicity and utility of the perfect or ideal gas calculations is readily apparent, imperfect or real gas behavior is also important. In the Appendixes, therefore, two headings are often found, i.e., ideal gas and real gas. We also include in this work polynomial fits for the second

and third virial coefficients. These allow accurate representation of non-ideal behavior at densities as high as 0.7 of the critical value⁶.

The material in this report is intended to be used in conjunction with standard reference texts on thermodynamics, fluid dynamics, and heat transfer. The user is encouraged, moreover, to discover for himself how the simple polynomial fits aid in the handling of differential equations with variable coefficients.

II. POLYNOMIAL CURVE FITS

The data source for Appendixes A, B, and C is the TRPC⁷⁻⁹ series. The virial coefficients are found in the American Institute of Physics Handbook, 3rd Edition¹⁰. These sources are considered to be among the most accurate. The TRPC series reproduce a large number of original sources and present a critically evaluated consolidation of available data. The accuracy of duplication of reference-source values is included with the polynomial equations as part of the format in the Appendixes [see pp. A-viii, B-iii, C-iii, and Dii]. References 7-9 include their own third-degree polynomial fits; other polynomial expressions are also available^{11,12} in most thermodynamic textbooks.

The most important consideration given in the curve fitting is the reliability of the data. Next to reliability, consideration is given to the greatest possible temperature range; reference source data are split along temperature intervals to achieve the most acceptable duplication accuracy. The equations presented are the lowest degree equations which achieve the desired accuracy over the temperature range stated.

III. POLYNOMIAL EVALUATIONS

For the calculation of properties or the inverse calculation of the temperature, we have relied almost exclusively on polynomial fits, with the exception of some specific heat [$C_p(T)$] forms which are exponential. The equations presented have the following forms:

Polynomial

$$FCTN(T) = B(0) + B(1)T + B(2)T^2 + \dots + B(N)T^N = \sum_{m=0}^N B(m)T^m$$

Exponential

$$\ln[FCTN(T)] = B(0) + B(1)T + \dots + B(N)T^N = \sum_{m=0}^N B(m)T^m$$

$$[\text{e.g., } C_p(T) = (\text{const}) \exp \left[\sum_{m=0}^N B(m)T^m \right]]$$

The most efficient method of evaluating single-variable polynomials is "nested multiplication"¹³. Nested multiplication eliminates the need to raise "X" to the "Y" power and simplifies an N-th order polynomial evaluation to a sequence of multiplication/addition steps. Examples of nested multiplication are presented below.

A. Generalized Nested Multiplication Algorithm:

Given the N coefficients, $B(0), B(1), B(2), \dots, B(N)$, for the polynomial function $FCTN(T)$ and any value of the temperature " T_i " within the range of validity

Set $A(N) = B(N)$ [e.g., $A(6) = B(6)$]

For $K = N, N-1, N-2, \dots, 1$, Do

Set $A(K-1) = B(K-1) + T_i A(K)$

$A(0) = FCTN(T_i)$

The above algorithm may be stated in words as follows: multiply the highest degree coefficient by the temperature value, T_i , and add to the next lower degree coefficient; multiply the sum by T_i and add to the next lower degree coefficient; multiply the sum by T_i ... Continue the process until the sum $B(1)+A(2)T_i$ is calculated; multiply this sum by T_i . By just adding the $B(0)$ coefficient to the previous product, the polynomial evaluation is completed for the chosen value of T_i .

B. Specific Example of Nested Multiplication:

Consider the calculation of the specific heat at constant pressure $[C_p(T)]$ for carbon dioxide (CO_2), ideal gas, at $800^{\circ}K$. From page A-9,

$$\begin{aligned} C_p(T) = & 453.86462 + 1.5334795T - 4.195556E-04 T^2 \\ & - 1.871946E-06 T^3 + 2.862388E-09 T^4 \\ & - 1.6962E-12 T^5 + 3.717285E-16 T^6 \end{aligned}$$

$$\text{Set } A(6) = 3.717285E-16 ; T = 800$$

Step-by-Step Procedures		Calculated Values		A(N)
(1)	$3.717285E-16$	$B(6)$	$= 3.717285E-16$	A(6)
(2)	X800	XT_i	$2.973828E-13$	
(3)	$-1.6962E-12$	$+B(5)$	$-1.3988172E-12$	A(5)
(4)	X800	XT_i	$-1.11905376E-09$	
(5)	$+2.862388E-09$	$+B(4)$	$1.74333424E-09$	A(4)
(6)	X800	XT_i	$1.394667392E-06$	
(7)	$-1.871946E-06$	$+B(3)$	$-4.77278608E-07$	A(3)
(8)	X800	XT_i	$-3.818228864E-04$	
(9)	$-4.195556E-04$	$+B(2)$	$-8.013784864E-04$	A(2)
(10)	X800	XT_i	-0.641102789	
(11)	$+1.5334795$	$+B(1)$	0.892376711	A(1)
(12)	X800	XT_i	713.9013687	
(13)	$+453.86462$	$+B(0)$	1167.765989	A(0)

Rounding to two decimal places, $A(0) = C_p(800K) = 1167.77 \text{ J/Kg K.}$

For programmable calculators, nested multiplication is extremely efficient and highly recommended. To preserve the add-multiply-add simplicity, negative coefficients should be stored as negative values.

IV. EXTRAPOLATION

With each polynomial equation there is a specified range of validity and an associated error estimate. The stated temperature range corresponds to that of the reference source. It is often highly desirable to know how the given polynomial expressions extrapolate. A limited polynomial extrapolation beyond the specified temperature range may often be possible but in indiscriminate extrapolation the accuracy will most likely suffer. In fact, polynomial fits are notoriously bad for certain type of curves outside of their specified range.

Clearly, it is inappropriate to look at every possible type of variation. Suffice it to say that for reasonably smooth, monotonic functions such as the viscosity, the thermal conductivity, and perhaps the heat capacity of polyatomic molecules, the polynomial fits will follow with some fidelity the trends outside of their specified range. If is anticipated that the heat capacity of diatomic molecules will be the most difficult for the polynomials to follow because of the "stepwise" nature of the curves^{14,15}. We have chosen to present the heat capacity of nitrogen as an example. The ideal gas polynomial fits are given on pg. A-41; we choose the curve for the temperature range 590-1365°K. As the basis of comparison, we pick the theoretical¹⁴ curve which represents the activation of the vibrational mode of the nitrogen molecule, using $\theta_v = 3390^\circ\text{K}$. Table I shows a listing of these calculations. It is seen that the polynomial results are within an acceptable $\pm 0.5\%$ for the temperature range 500°K to 1600°K. Above and below this range the polynomial results quickly diverge, as more or less anticipated. Certainly, a useful rule may be to stay within 100°K of the guaranteed range.

TABLE I

POLYNOMIAL COMPARISON, C_p FOR NITROGEN

T (K)	CP/R THEO	CP/R POLY	%DIFF
400	3.51513	3.55253	-1.06371
500	3.55272	3.56516	- .35014
600	3.6137	3.62092	- .199842
700	3.68868	3.69739	- .236274
800	3.76795	3.77981	- .314853
900	3.84486	3.85952	- .381236
1000	3.91588	3.9325	- .424339
1100	3.97859	3.99775	- .456325
1200	4.03582	4.05591	- .497772
1300	4.08501	4.10757	- .552173
1400	4.12787	4.15159	- .574591
1500	4.16518	4.18432	- .45953
1600	4.19768	4.19665	.024718
1700	4.22606	4.17417	1.22786
1800	4.2509	4.09448	3.67977

The reader might ask at this point why bother with a polynomial when an exact expression is available. The answer to this question is two-fold: First, reliable analytical expressions are not available for most of the properties and, second, when available they tend to be much more cumbersome than the polynomial expressions presented here.

V. ITERATIVE METHODS

It is often necessary to calculate the temperature from the known value of a property. This inverse problem is handled two ways, either a polynomial fit is given in Appendixes A, B, and C for the calculation of the absolute temperature as a function of the property or an iterative procedure is suggested. In this section we discuss such iterative methods.

Before proceeding, however, it is worth noting that when a second degree polynomials in T is given for the inverse calculation, the quadratic formula may be applied. If it works, this is by far the quickest way to a solution.

The polynomials presented have the absolute temperature (T) as the single independent variable and the property value (PV) as the dependent variable. $FCTN(T_i)$ becomes the magnitude of the property value (PV) when the polynomial function is evaluated at $T = T_i$. Thus, $FCTN(T_i) = |PV|$ at $T = T_i$. To enhance the usefulness of this work, three methods are provided for the calculation of temperature (T) as a function of a known or given property value, PV. The methods are (A) secant method, (B) Newton's method, and (C) fixed point iteration¹⁶. All three methods are iterative in nature.

The general form of the polynomials is

$$FCTN(T_i) = B(0) + B(1)T_i + B(2)T_i^2 + \dots + B(N)T_i^N$$

The iterative methods attempt to solve for the approximate root (the temperature) of the equation of the form

$$F(T_i) = PV - B(0) - B(1)T_i - B(2)T_i^2 - \dots - B(N)T_i^N = 0$$

All of the polynomials are both continuous and continuously differentiable over the temperature intervals specified. Although these conditions are necessary for iterative methods to converge to an approximate root,

they are not necessarily sufficient in all cases to assure convergence. Enough testing has been done with the polynomials presented, however, to give reasonable assurance of convergence with any of the three methods discussed.

The quadratic formula for the second degree polynomial is simply

$$T = \frac{-B(1) + \sqrt{B(1)^2 - 4 B(2)[B(0) - PV]}}{2 B(2)}$$

A. Secant or Interpolation Method^{13,16}:

When it converges, the secant method does so very rapidly, generally more rapidly than either of the other two iterative methods discussed. Two initial values (guesses) for the temperature are required, T_{-1} and T_0 . The initial temperature values selected may be the extremes of the valid temperature range noted with the polynomial sets.

Algorithm: Given $(T_i) = 0$ and two (2) initial points, T_{-1} and T_0

For $n = 0, 1, 2, \dots$ until satisfied, do

$$\text{Calculate } T_{n+1} = T_n - F(T_n) \frac{(T_n - T_{n-1})}{F(T_n) - F(T_{n-1})}$$

In the special case when second degree polynomials given in the Appendix, the secant method algorithm reduces to:

For $n = 0, 1, 2, \dots$ until satisfied, do

$$\text{Calculate } T_{n+1} = T_n - \frac{B(0) + B(1)T_n + B(2)T_n^2 - (PV)}{B(1) + B(2)(T_n + T_{n-1})}$$

Specific Example: Consider a second (2nd) degree polynomial for $C_p(T)$: $FCTN (T_i) = 0.232829 + 1.43429E-05T_i + 3.56638E-09T_i^2$. Assume a given property value $C_p = 0.2567$ but the temperature is unknown. The

known property value (PV) is 0.2567 and T_{-1} and T_0 are chosen arbitrarily at 200 and 2400 respectively. The following solution is provided:

n	T_{n-1}	T_n	T_{n+1}
0	200	2400	-
1	2400	2400	1411.67
2	2400	1411.67	1286.97
3	1411.67	1286.97	1266.32
4	1286.97	1266.32	1265.87
5	1266.32	1265.87	1265.87* Convergence

$$T_i = 1265.87 \text{ for } C_p(T_i) = 0.2567$$

B. Newton's Method¹⁶:

Newton's method requires a single initial value for temperature, T_0 , and the first derivative of the polynomial function, $F(T_i) = 0$. Newton's method tends to be sensitive to the T_0 selection, the closer T_0 is to the root, T_i , the more rapid it converges. For the polynomials presented, Newton's method generally converges without problems. It is recommended that the initial temperature value, T_0 , be selected mid-range between the polynomial valid temperature limits.

Algorithm: Given $F(T_i) = 0$ and a starting value, T_0

For $n = 0, 1, 2, \dots$ until satisfied, do

Calculate $T_{n+1} = T_n - F(T_n)/F'(T_n)$

For the special case of using a second degree polynomial from Appendix A, Newton's method reduces to the following:

For $n = 0, 1, 2, \dots$ until satisfied, do

Calculate $T_{n+1} = T_n - \frac{B(0) - (PV) + B(1)T_n + B(2)T_n^2}{B(1) + 2B(2)T_n}$

C) Fixed Point Iteration:¹⁶

Fixed point iteration tends to converge the slowest of the three methods discussed. It does, however, provide the user with the function definition. Given the function, $F(T_i) = 0$, the user defines an iterative function, $T = g(T_i)$, such that the solution of the iterative function is also the solution to $F(T_i) = 0$.

Example: Given $F(T_i) = 0 = B(0) + B(1)T_i + B(2)T_i^2$ - (PV)

$$\text{Then } T_i = g_i(T) = \frac{(PV) - B(2)T_i^2 - B(0)}{B(1)}$$

$$\text{Or } T_i = \left(\frac{(PV) - B(0) - B(1)T_i}{B(2)} \right)^{1/2}$$

Algorithm: Given $F(T_i) = 0$, a derived iterative function $g(T)$, and a single starting point, T_0

For $n = 0, 1, 2, \dots$ until satisfied, do

Calculate $T_{n+1} = g(T_n)$

VI. CONCLUSIONS

Within the constraints of a single independent variable (the absolute temperature), it is possible to calculate thermodynamic and transport properties of a large variety of gases accurately. The accuracy of the polynomial results is generally within $\pm 0.5\%$ of the original tabular data. Since interpolation is "build-in", the effort is often no more time consuming than that of reading conventional tabular forms. The inverse problem, namely that of finding the temperature corresponding to a given property, can also be accurately carried out with the information given in this report.

Extrapolation beyond the established valid temperature range is possible but the accuracy of duplication of the property is dubious and cannot be quantified in most cases. The polynomials, however, do allow for a convenient "first guess" in most instances.

It is believed that the combination of simple polynomial representations with the technique of nested multiplication utilized in a modern electronic calculator will make the Gas Tables and other standard works obsolete in form. Integration and differentiation of the polynomials is, moreover, straightforward and virtually risk free so that they are attractive forms for numerical work, particularly with ideal gases. The advantages of simple polynomial representations become vividly clear when other correlation-equation forms are used, see for example the form of the viscosity given in Ref. 5 or 17.

APPENDIX A
FORMAT EXAMPLE

The equations presented are for gaseous Acetylene (ideal gas)

The polynomial equation to calculate the specific heat (C_p) in J/Kg K as a function of temperature (Kelvin)

	Formula	Valid temperature range
-ACETYLENE - Ideal gas	C_2H_2	<u>275-755K</u>
$C_p(T) = 399.896066 + 6.226492T - 7.433125E-03T^2 + 3.4974695E-06T^3$		
$C_p(275) = 1622.79$	$C_p(450) = 2015.32$	$C_p(755) = 2369.03$
std error est = 0.111		max error est = 1.0
	<u>755-1365K</u>	
$C_p(T) = 1321.969854 + 1.9041159T - 7.913804E-04T^2 + 1.403319E-07T^3$		
$C_p(755) = 2368.87$	$C_p(1000) = 2575.04$	$C_p(1365) = 2803.47$
std error est = 0.111		max error est = 1.0

	<u>275-1365K</u>	
$T(C_p) = 1717.26917 - 1.9064232C_p + 6.3328193E-04C_p^2$		
$T(1622.79) = 291$	$T(2368.87) = 755$	$T(2803.47) = 1350$
std error est = 5		max error est = 15
standard (or average) error estimate is ±5 degrees Kelvin		

The polynomial equation to calculate temperature (Kelvin) as a function of specific heat (C_p) in J/Kg K

Using the polynomial presented, the calculated specific heat at 755K is 2369.03 J/Kg K.

Over the temperature range noted, the maximum error est is ±1 J/Kg K.

FIGURE A-1

APPENDIX A

SPECIFIC HEAT AT CONSTANT PRESSURE FOR GASEOUS ELEMENTS AND COMPOUNDS

ACETONE - Ideal gas C₃H₆O 275-1365K

$$C_p(T) = 345.6240845 + 3.1344046T + 9.000608E-04T^2 - 1.9981015E-06T^3 \\ - 7.2481823E-10T^4 + 1.757756E-12T^5 - 5.94192596E-16T^6$$

$$C_p(275) = 1232.46 \quad C_p(700) = 2346.88 \quad C_p(1365) = 3189.13 \\ \text{std error est} = 0.791 \quad \text{max error est} = 1.25$$

275-1365K

$$T(C_p) = -537.70187 + 1.08064298C_p - 4.673706E-04C_p^2 + 9.857246E-08C_p^3$$

$$T(1232.46) = 269 \quad T(2346.88) = 698 \quad T(3189.13) = 1352$$

$$\text{std error est} = 3 \quad \text{max error est} = 13$$

ACETYLENE - Ideal gas C₂H₂ 275-755K

$$C_p(T) = 399.896066 + 6.226492T - 7.433125E-03T^2 + 3.4974695E-06T^3$$

$$C_p(275) = 1622.79 \quad C_p(450) = 2015.32 \quad C_p(755) = 2369.03 \\ \text{std error est} = 0.111 \quad \text{max error est} = 1.0$$

755-1365K

$$C_p(T) = 1321.969854 + 1.9041159T - 7.913804E-04T^2 + 1.403319E-07T^3$$

$$C_p(755) = 2368.87 \quad C_p(1000) = 2575.04 \quad C_p(1365) = 2803.47$$

$$\text{std error est} = 0.111 \quad \text{max error est} = 1.0$$

275-1365K

$$T(C_p) = 1717.26917 - 1.9064232C_p + 6.3328193E-04C_p^2$$

$$T(1622.79) = 291 \quad T(2368.87) = 755 \quad T(2803.47) = 1350$$

$$\text{std error est} = 5 \quad \text{max error est} = 15$$

AIR - Ideal gas 100-590K

$$C_p(T) = 1022.5294853 - 0.1758625T + 4.020605E-04T^2 - 4.8640623E-08T^3$$

$$C_p(100) = 1008.92 \quad C_p(350) = 1008.14 \quad C_p(590) = 1048.74$$

$$\text{std error est} = 0.012 \quad \text{max error est} = 0.025$$

590-1365K

$$C_p(T) = 928.911894 + 0.0897769T + 3.2460657E-04T^2 - 2.62542E-07T^3$$

$$+ 5.99901E-11T^4$$

$$C_p(590) = 1048.22 \quad C_p(1000) = 1140.74 \quad C_p(1365) = 1196.81$$

$$\text{std error est} = 0.22 \quad \text{max error est} = 0.5$$

590-1365K

$$T(C_p) = -100444.9907 + 275.16644C_p - 0.253212C_p^2 + 7.885293E-05C_p^3$$

$$T(1048.22) = 588 \quad T(1140.74) = 998 \quad T(1196.81) = 1361$$

$$\text{std error est} = 1.5 \quad \text{max error est} = 4$$

Note: For T(C_p) calculations below 590K use the iterative procedures discussed in Section 5 and the following polynomial: 100-590K,

$$C_p(T) = 1021.17215 - 0.1603904T + 3.5182525E-04T^2.$$

AIR - Real gas

255-865K

$$Cp(T) = 1052.71406 - 0.3745355T + 8.361477E-04T^2 - 3.32111E-07T^3 - 4.683905E-11T^4$$

$$Cp(255) = 1005.87 \quad Cp(560) = 1042.26 \quad Cp(865) = 1113.2$$

std error est = 0.17 max error est = 0.4

Note: For T(Cp) calculations use the iterative procedures discussed in Section 5 and the following polynomial: 255-865K, $Cp(T) =$

$$- 996.831581 - 0.0322256T + 2.0181265E-04T^2. - - - - -$$

AMMONIA - Ideal gas NH₃ 220-590K

APPENDIX B
FORMAT EXAMPLE

The equations presented are for gaseous Acetylene

The polynomial equation to calculate the thermal conductivity (k) in W/m K as a function of temperature (Kelvin)

Using the polynomial presented, the calculated thermal conductivity at 650K is 0.0619 W/m K.

Over the temperature range noted, the maximum error est is $\pm 7E-04$ W/m K.

-ACETYLENE	Formula	Valid temperature range
	C_2H_2	<u>200-650K</u>
	$k(T) = -8.5510082E-02 + 1.461749E-03T - 9.4040526E-06T^2$ $+ 3.242075E-08T^3 - 5.91795705E-11T^4 + 5.4937859E-14T^5$ $- 2.04661826E-17T^6$

---	--

standard (or average) error estimate is ±0.3 degrees Kelvin

The polynomial equation to calculate temperature (Kelvin) as a function of dynamic viscosity in N s/m²

Using the polynomial presented, the calculated dynamic viscosity at 600K is 19.12E-06 N s/m²

Over the temperature range noted, the maximum estimated error is ±0.01E-06N s/m².

***Note: All of the values for dynamic viscosity (μ) MUST be multiplied by 1E-06.

Methane	CH ₄	D-2
Neon	Ne	D-3
Nitrogen	N ₂	D-3
Oxygen	O ₂	D-3
Water Vapor	H ₂ O	D-4
'Heavy' Water Vapor	D ₂ O	D-4
Xenon	Xe	D-4
TABLE D-II Third Virial Coefficients		D-5

APPENDIX D
FORMAT EXAMPLE

The equation/s is for gaseous Neon	Using the polynomial presented, the calculated second virial coefficient at 200K is 7.60 cm ³ /mol.	
-The polynomial equation to calculate the SECOND virial coefficient [B(T)] in cm ³ /mol as a function of temperature (Kelvin)	Over the temperature range noted, the maximum error est is ±0.08 cm ³ /mol.	
	Formula	Valid Temperature Range
NEON	Ne	80-200K
	$B(T) = -108.0286 + 2.354366T - 2.011992E-02T^2 + 8.1876808E-05T^3 - 1.28414363E-07T^4$	$B(200) = 7.60$
	$B(80) = -11.79$	$B(140) = 2.57$
std error est = 0.04		max error est = 0.08
The standard (or average) error estimate over the temperature range noted is ±0.04 cm ³ /mol.
